Outline

Multiple Testing

In many testing problems, we want to test many hypotheses at a time, e.g. • Test H_{oj} : $B_j = 0$ for j = 1, ..., d in linear regression · Test whether each of 2M single nucleotide polymorphisms (SNPs) is associated with a given phenotype (e.g., diabetes / schizophrenia) · Test whether each of 2000 web site tweaks affects user engagement Setup: $X \sim P_{\theta} \in \mathcal{P}$ $H_{\sigma i}: \Theta \in \bigoplus_{\sigma i}, i=1,..., m$ (Commonly, $H_{oi}: \Theta_i = 0$) Goal: Return accept/reject decision for each i. Let $\chi(x) = \{i : H_{oi} \text{ rejected}\} \in \{1, ..., m\}$ $\mathcal{H}_{o}(0) = \{i : H_{oi} \text{ true }\}$ $R(x) = |\mathcal{R}(x)|, \quad m_0 = |\mathcal{H}_0|$

Family wise Error Rate

Problem: Even if all Hoi true, might have IP (any Hoi rejected) >> ~ $\underbrace{\mathsf{E}_{X}}_{i} \xrightarrow{ind} \mathsf{N}(\Theta_{i}, i) \quad i = 1, \dots, m, \quad H_{ai} : \Theta_{i} = 0$ 10 (any Hoi rejected) = 1 - (1 - a) -> 1 Is this a problem? Yes, if all attention will be focused on the (false) rejections and none on the (correct) non-rejections. Classical solution is to control the familywise error rate (FWER): FWERO = Po(any false rejections) $= \mathbb{P}_{\Theta}(\mathcal{R} \cap \mathcal{H}_{\sigma} \neq \emptyset)$ sup FWERD E « Wort Typically achieved by "correcting marginal H. $p-values p_1(x), \dots, p_m(x)$ $(p_2 \stackrel{H_2}{\cong} U[0,1])$ e.g., $p_i(x) = \lambda(1 - \overline{D}(1x_i))$ for Gaussian

$$\frac{\text{Ronferron: Correction}}{\text{Assume } p_{1,...,p_{m}} \text{ are } p_{-vilues } \text{ for } H_{0,1..., } \text{ Hom } with p_{i} \equiv U[0,1] \text{ under } H_{0i}}$$
For general dependence, can guarantee control by rejecting Hoi iff $p_{i} \leq \gamma_{m}$:
$$\frac{R_{0}(\text{ any false rejections})}{= R_{0}((U \in H_{0i} \text{ rejected}))}$$

$$\leq \sum_{i \in H_{0}} R_{0}((H_{0i} \text{ rejected}))$$

$$\leq M_{0} \cdot \gamma_{m} \leq d$$
If $p_{-values independent, can improve to $\tilde{a}_{n} = 1 - (1 - \pi)^{V_{m}}$ (Sidak correction)
Then $R_{0}(\text{ no filse rejections})$$

If p-values independent, can improve to

$$\tilde{a}_n = 1 - (1 - \alpha)^{V_m}$$
 (Šidák correction)
Then $R_{\alpha}(no)$ fulse rejections)

Then
$$IP_{\Theta}(no filse rejections)$$

= $TT_{\Theta}(p_i = \tilde{a}_m)$
 $i \in \mathcal{H}_0 P_{\Theta}(p_i = \tilde{a}_m)$
 $\geq (1 - \tilde{a}_m)^{m_0} \geq 1 - d$

For small α , $1 - \tilde{\alpha}_{m} = (1 - \alpha)^{\prime m} \approx 1 - \frac{\alpha'}{m}$ =) Sidak doesn't improve much on Bonferroni

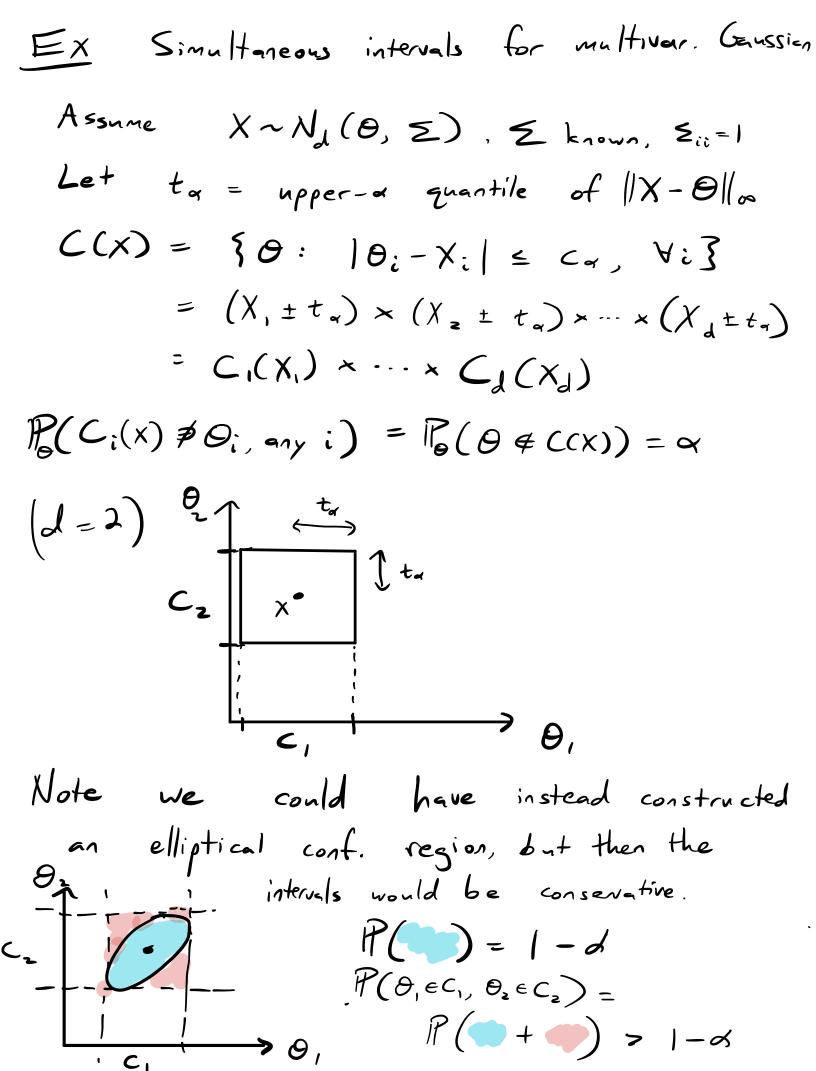

Bonferroni isn't much worse than Šidāk, e.g. 9=5% m=20: .0025 vs.00256

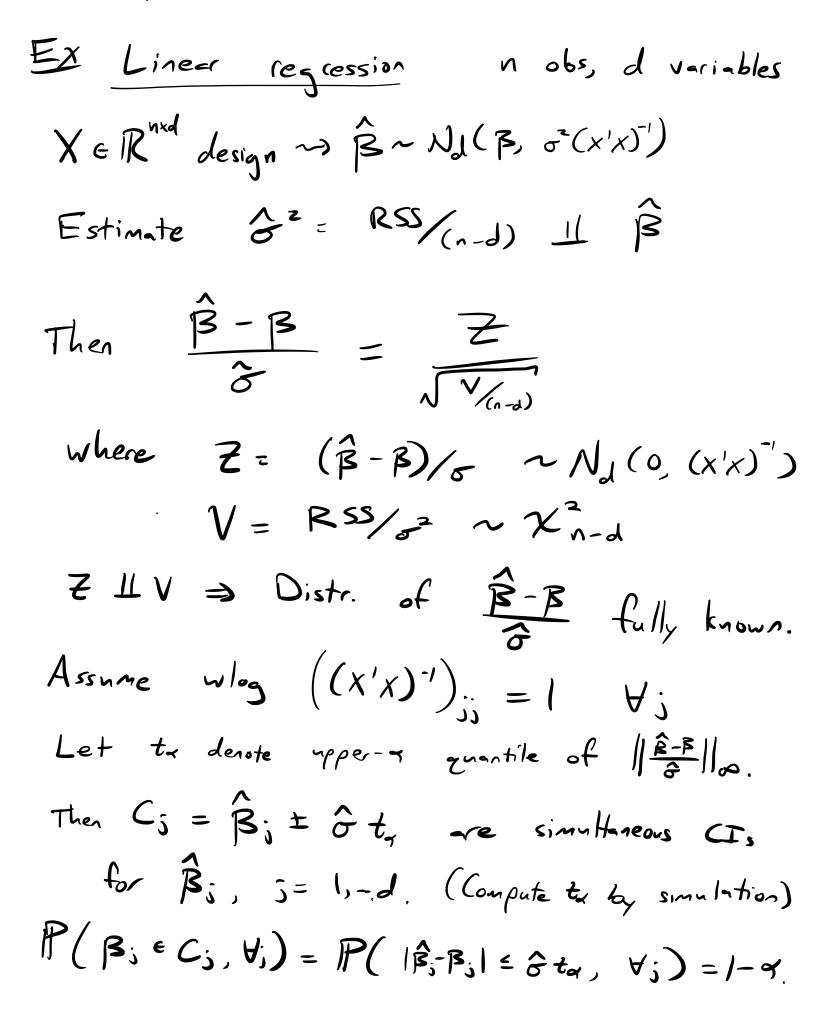

- But when tests are highly dependendent, can often do <u>much</u> better.
- Ex. Scheffe's S-method $X \sim N_1(\Theta, I_d) \quad \Theta \in \mathbb{R}^d$ $H_{o,\lambda}: \Theta' \lambda = O$ for $\lambda \in S^{d-1}$ ("m" = ∞) (+= 5%) Reject $H_{0,\lambda}$ if $\|X'\lambda\|^2 \ge \mathcal{K}_{J}^{2}(\alpha) \approx d+3Jd$ Controls FWER: $\sup_{\lambda: \theta' \lambda = 0} \|\chi' \lambda\|^{2} \leq \sup_{\lambda} \|(\chi - \theta)' \lambda\|^{2} \sim \chi_{d}^{2}(\alpha)$ deduction from confidence region Can view م 2 $((X) = \{ \Theta : \|\Theta - X\|^2 \in \chi_d^2(q) \}$

Deduced inference
Given any joint confidence region
$$C(x)$$

for $\Theta \in \Theta$, we may freely assume
 $\Theta \in C(x)$ and "deduce" any and all
implied conclusions without any FWER inflation
 $P_{\Theta}(any \ deduced \ inference \ is \ wrong)$
 $= P_{\Theta}(\Theta \notin C(x)) \leq \alpha$

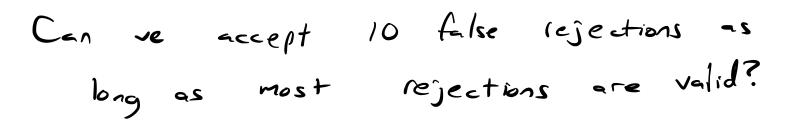

We say
$$C_{i}(X), \dots, C_{m}(X)$$
 are
simultaneous 1-a confidence intervals
for $g_{i}(0), \dots, g_{m}(0)$ if
 $P_{0}(g_{i}(0) \in C_{i}(X), \forall i = 1, \dots, m) \geq 1-\alpha$

False Discovery Rate (FDR)

Motivation: Suppose we test 10,000 hypotheses with independent test statistics, all at level $\alpha = 0.001$. We expect 10 rejections just by chance. What if we get 50? Probably only & 20% of them are fake rejections.

$$R(X) = \# Q(X) \qquad \# rejections/ Siscoveries$$

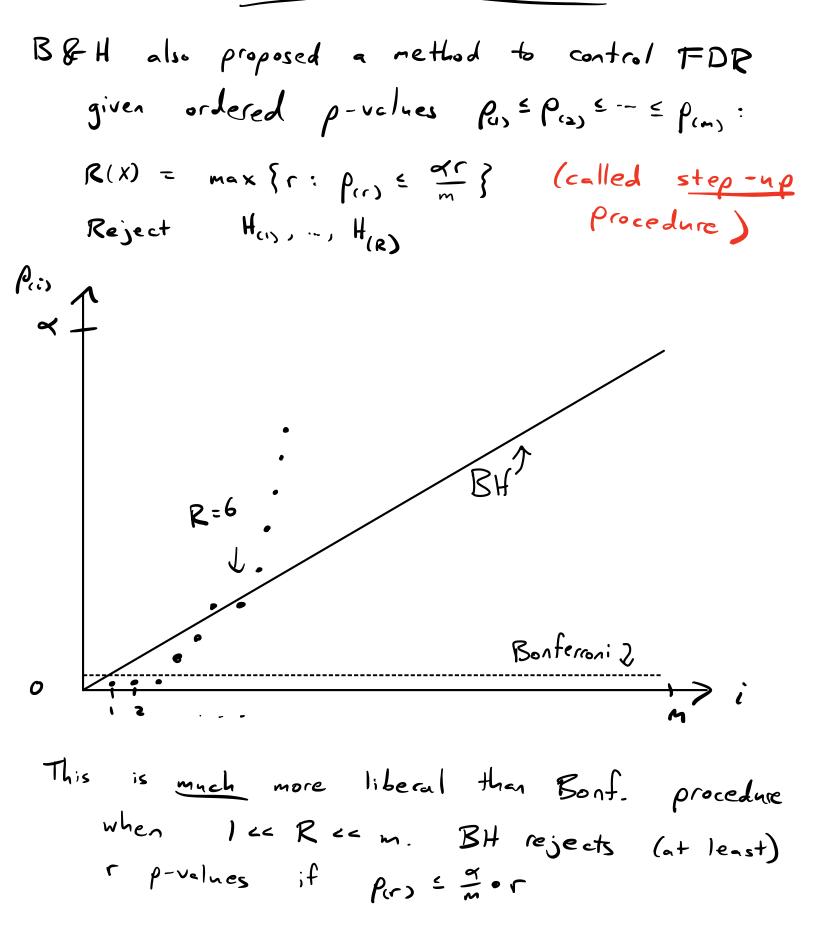

$$V(X;\theta) = \# (Q(X) \cap \mathcal{H}_{0}(\theta)) \qquad \# filse discoveries$$

$$The false discovery propertion (FDP) is$$

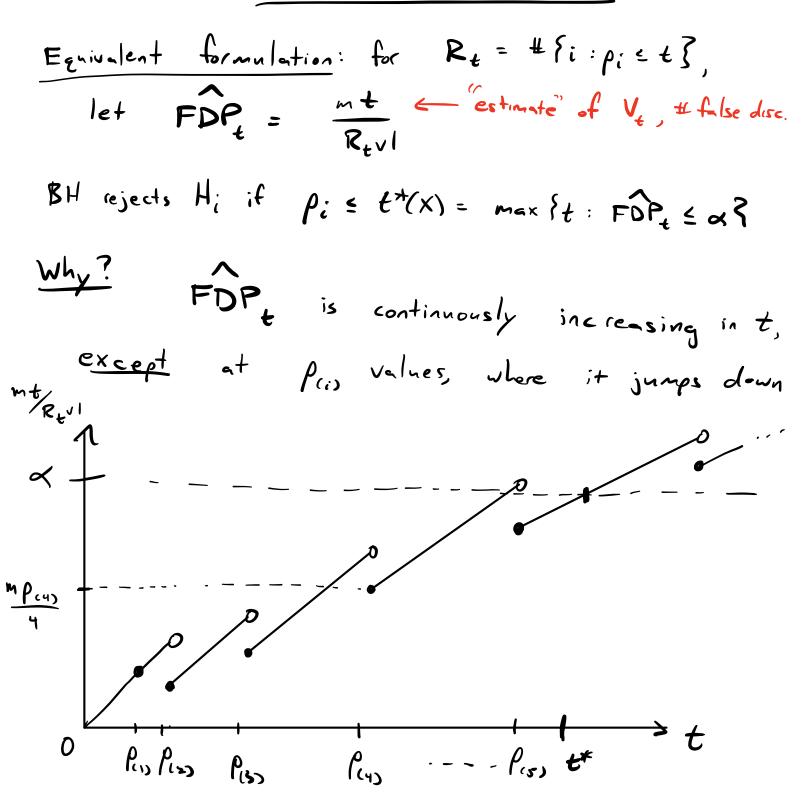

$$FDP = \frac{V}{R} \qquad \text{where} \qquad \mathcal{H} \stackrel{e}{=} 0 \quad (\frac{V}{R \cup 1})$$

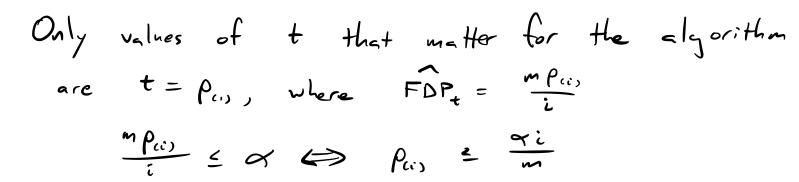

$$The FDR is \qquad \mathbb{E}[FDP] = \mathbb{E}_{\theta}[\frac{V}{R \cup 1}]$$

Benjamini - Hochberg Procedure

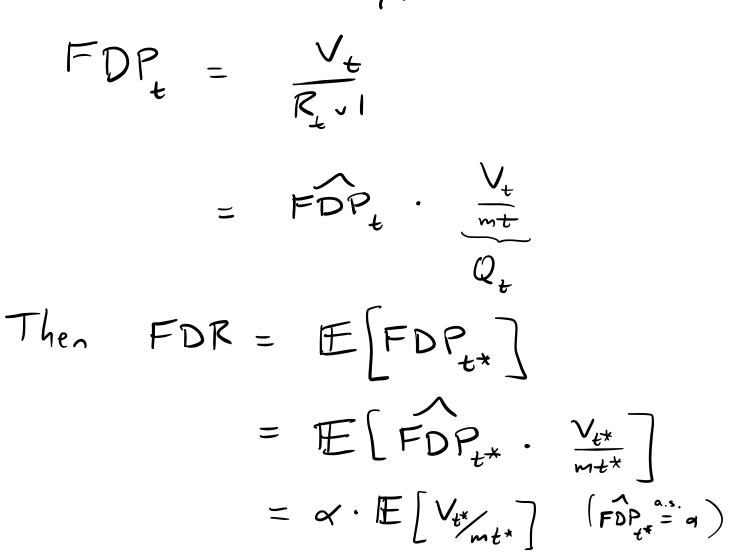

$$FDR \quad control$$

$$Elegant (but fragilo) proof due to Storey,$$
Taylor, & Sigmund (2002)
$$Assume \quad p_i \quad indep. , \quad p_i \sim U[0,1] \quad i \in \mathcal{H}_o$$

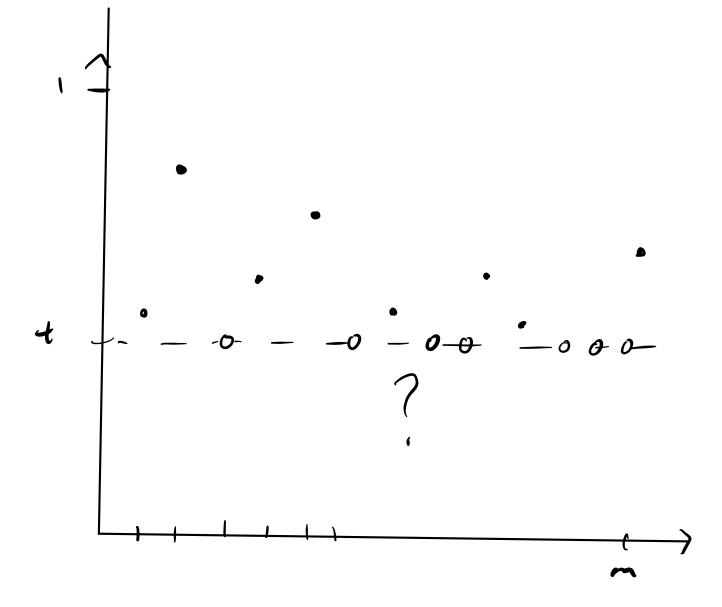

$$Let \quad V_t = \#\{i \in \mathcal{H}_o : p_i \in t\}$$

$$FDP \qquad V_t$$

Note Qt is a martingale when truns backwards from t=1 to t=0: **S** < t : $E[V_s | V_t = v]$ $= \mathbb{E}\left[\#\left\{i: p_{i} \leq s\right\} \mid \#\left\{i: p_{i} \leq t\right\} = v\right]$ $= v \cdot \frac{s}{t}$ $F\left(\frac{V_s}{ms} \mid \frac{V_t}{mt} = q\right) = \frac{1}{ms} \cdot (q_mt) \cdot \frac{s}{t} = q$ And t* is a stopping time wit the filtration $\mathcal{F}_{t} = \sigma(\rho, vt, \dots, \rho_{m}vt)$ (again, filtration with k=1 > t=0) Why? For szt, $R_s = \#\{i: p_i \leq s\}$ = $\#\{i: p_i \lor t \leq s\}$

$$FDP_{s} = \frac{ns}{R_{s}}$$

 $FDR = \propto E[V_{t^*}]$ $= \propto E[V_{m}]$ $= \sigma m_{m}$

Remarks

• FDR controlled under general dependence
if we use corrected level
$$= \frac{1}{L_m}$$
,
 $L_m = \sum_{i=1}^{m} \frac{1}{i} \approx \log(m)$
